

## OUTLINE

The R1285L 2ch DC/DC converter is designed for OLED Display power source. It contains a step up DC/DC converter and an inverting DC/DC converter to generate two required voltages by OLED Display.

Step up DC/DC converter generates boosted output voltage to 4.6V ~ 5.0V. Inverting DC/DC converter generates negative voltage -2.0V ~ -6.0V independently. Each of the R1285 series consists of an oscillator, a PWM control circuit, a voltage reference, error amplifiers, over current protection circuits, short protection circuits, an under voltage lockout circuit (UVLO), a complete shutdown switch and an Nch driver for boost operation, a Pch driver for inverting, and so on. A high efficiency boost and inverting DC/DC converter can be composed with external inductors, diodes, capacitors and resistors. Start up sequence is internally made.

## FEATURES

- Operating Voltage ••••• 2.3V ~ 4.8V
- Step Up DC/DC (CH1)
  - Internal Pch MOSFET for complete shutdown (Ron=300mΩTyp.)
  - Internal Nch MOSFET Driver (Ron=300mΩTyp.)
  - Output Voltage (V<sub>OUTP</sub>) ••••• 4.6V ~ 5.0V (0.2VStep)
  - Auto Discharge function for positive output
  - Internal Soft start function (Typ. 4.5ms)
  - Over Current Protection
  - Maximum Duty Cycle: 85%(Typ.)
- Inverting DC/DC (CH2)
  - Internal Pch MOSFET Driver (Ron=600mΩ Typ.)
  - Output Voltage (V<sub>OUTN</sub>) ••••• -2V ~ -6V (0.1VStep) [ R1285LxxxA ]
  - Adjustable Vout Up to -6V with external resistors [ R1285L00xB ]
  - Auto Discharge function for negative output
  - Internal Soft start function (Typ. 4.5ms)
  - Over Current Protection
  - Maximum Duty Cycle: 90%(Typ.)
- Control
  - Short Protection with timer latch function (Typ. 50ms)
    - Short condition for either or both two outputs makes all output drivers off and latches. If the maximum duty cycle continues for a certain time, these output drivers will be turned off. This function prevents irregular current from overheating the R1285 .
  - CE with start up sequence function ( CH1→CH2 )
  - UVLO function.
  - Operating Frequency ••••• 1400kHz
- Small package ••••• DFN12 ( 2.7mm x 3.0mm )

## APPLICATION

- Fixed voltage power supply for portable equipment
- Fixed voltage power supply for OLED

Operating Temperature Range	T <sub>a</sub>	-40 ~ +85	°C
Storage Temperature Range	T <sub>stg</sub>	-55 ~ +125	°C

\*1) For Power Dissipation, please refer to PACKAGE INFORMATION to be described.

\*2) In case the voltage range is from -0.7V to -0.3V, permissible current is 10mA or less.

### ABSOLUTE MAXIMUM RATINGS

Absolute Maximum ratings are threshold limit values that must not be exceeded ever for an instant under any conditions. Moreover, such values for any two items must not be reached simultaneously. Operation above these absolute maximum ratings may cause degradation or permanent damage to the device. These are stress ratings only and do not necessarily imply functional operation these limits.

\* In terms of TST pin(TST1, TST2), connect the GND level or remain it open.

#### RECOMMENDED OPERATING CONDITIONS (ELECTRICAL CHARACTERISTICS)

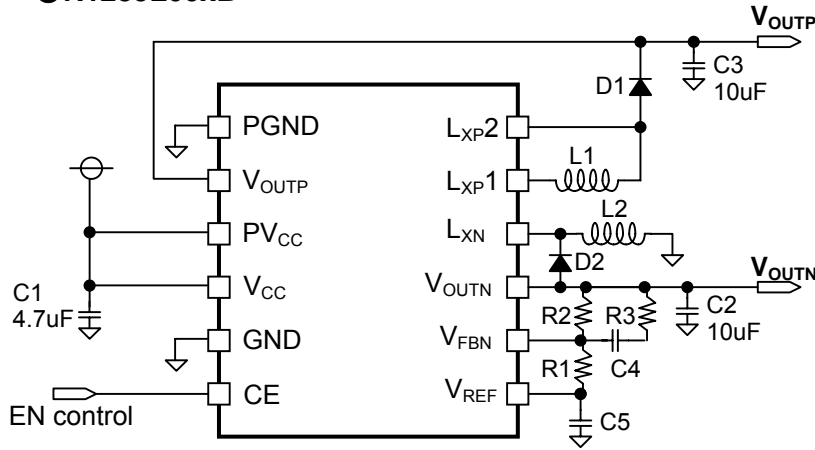

All of electronic equipment should be designed that the mounted semiconductor devices operate within the recommended operating conditions. The semiconductor devices cannot operate normally over the recommended operating conditions, even if when they are used over such conditions by momentary electronic noise or surge. And the semiconductor devices may receive serious damage when they continue to operate over the recommended operating conditions.

TYPICAL APPLICATION AND TECHNICAL NOTES

●R1285LxxxA

●R1285L00xB

●Set a ceramic 4.7μF or more capacitor between Vcc and GND as C1.

●Set a ceramic 10μF or more capacitor between V\_OUTP and GND, and between V\_OUTN and GND for each as C2 and C3.

●Start up Sequence

When CE level turns from 'L' to 'H' level, the softstart of CH1 starts the operation. After detecting output voltage of CH1 (V\_OUTP) as the nominal level, the soft start of CH2 starts the operation.

### ● Auto Discharge Function

When CE level turns from 'H' to 'L' level, the R1285 goes into standby mode and switching of the outputs of  $L_{XP2}$  and  $L_{XN}$  will stop. Then discharge switch between  $V_{OUTN}$  and  $PV_{CC}$  and switch between  $V_{OUTP}$  and GND turn on and discharge the negative output voltage and positive output voltage. When the negative output voltage is discharged to 0V, the switch between  $V_{OUTN}$  and  $PV_{CC}$  turns off and the negative output will be Hi-Z. Positive output voltage is discharged to 0V In standby mode.

If  $V_{CC}$  voltage became lower than UVLO detect voltage, discharge switches also turn on and discharge output voltage ( $V_{OUTN}$  and  $V_{OUTP}$ ).

In case of timer latch protection, discharge switches will keep off.

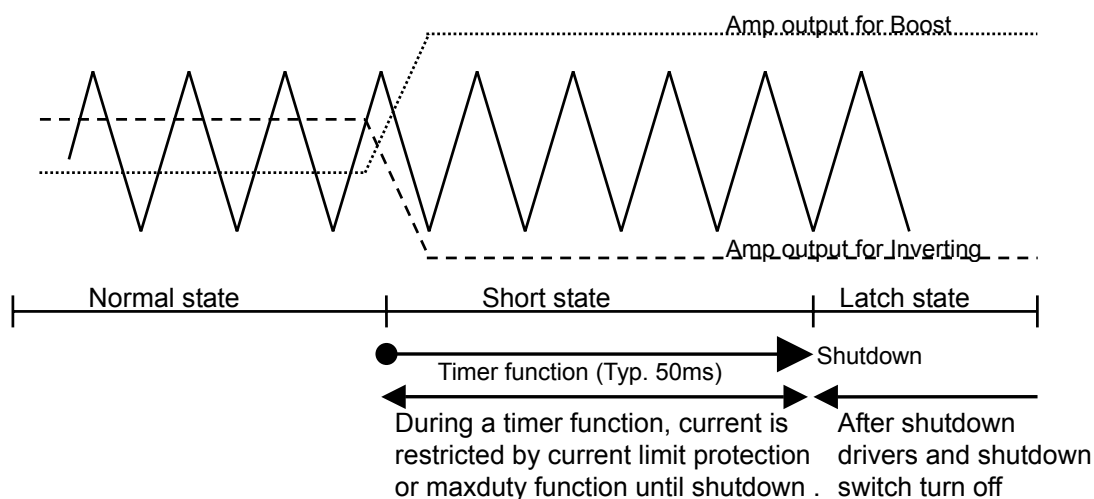

### ● Short protection circuit timer

In case that the voltage of  $V_{OUTP}$  drops, the error amplifier of CH1 outputs "H". In case that the voltage of  $V_{OUTN}$  rises, the error amplifier of CH2 outputs "L". The built-in short protection circuit makes the internal timer operate with detecting the output of the error amplifier of CH1 as "H", or the output of the error amplifier of CH2 as "L". After the setting time will pass, the switching of  $L_{XP2}$  and  $L_{XN}$  will stop and shutdown switch will turn off and both of discharge switches will keep off.

To release the latch operation, make the  $V_{CC}$  set equal or less than UVLO level and restart or set the CE pin as "L" and make it "H" again.

During the softstart operation of CH1 and CH2, the timer operates independently from the outputs of the error amplifiers. Therefore, even if the softstart cannot finish correctly because of the short circuit, the protection timer function will be able to work correctly.

●Inverting DC/DC converter output voltage setting [ R1285L00xB ]

The output voltage  $V_{OUTN}$  of the inverting DC/DC converter is controlled with maintaining the  $V_{FBN}$  as 0V.  $V_{OUTN}$  can be set with adjusting the values of R1 and R2 as in the next formula.

$$V_{OUTN} = V_{FBN} - (V_{REF} - V_{FBN}) \times R2 / R1$$

DC/DC converter's phase may lose 180 degree by external components of L and C and load current. Because of this, the phase margin of the system will be less and the atability will be worse. Therefore, the pahse must be gaind.

A pole will be formed by external components, L and C.

$$F_{pole} \sim 1 / \{2 \times \pi \times \sqrt{(L2 \times C2)}\}$$

Zero will be formed with R2 and C4.

$$F_{zero} \sim 1 / (2 \times \pi \times R2 \times C4)$$

Set the cutt-off frequency of the Zero close to the cutt-off frequency of the pole by L and C.

If the noise of the system is large, the output noise affects the feedback and the operation may be unstable. In that case, another resistor R3 will be set. The appropriate value range is from 1kΩ to 5kΩ.

●Set a ceramic 1μF to 2.2μF capacitor between  $V_{REF}$  and GND as C5. [ R1285L00xB ]

Operation of Step-up DC/DC Converter and Output Current

There are two operation modes for the PWM control step-up switching regulator, that is the continuous mode and the discontinuous mode.

When the LX Tr. is on, the voltage for the inductor L will be  $V_{IN}$ . The inductor current ( $IL1$ ) will be;  
 $IL1 = V_{IN} \times T_{on} / L$  .....Formula1

When the Lx transistor turns off, power will supply continuously. The inductor current at off ( $IL2$ ) will be;  
 $IL2 = (V_{OUT}-V_{IN}) \times T_{f} / L$  .....Formula2

In terms of the PWM control, when the  $T_f=T_{off}$ , the inductor current will be continuous, the operation of the switching regulator will be continuous mode.

In the continuous mode, the current variation of  $IL1$  and  $IL2$  are same, therefore  
 $V_{IN} \times T_{on} / L = (V_{OUT}-V_{IN}) \times T_{off} / L$  .....Formula3

In the continuous mode, the duty cycle will be  
 $DUTY = T_{on} / (T_{on}+T_{off}) = (V_{OUT}-V_{IN}) / V_{OUT}$  .....Formula4

If the input power equals to output power,  
 $I_{OUT} = V_{IN}^2 \times T_{on} / (2 \times L \times V_{OUT})$  .....Formula5

When  $I_{OUT}$  becomes more then Formula5, it will be continuous mode.

In this moment, the peak current,  $ILx_{max}$  flowing through the inductor is described as follows:

$ILx_{max} = I_{OUT} \times V_{OUT} / V_{IN} + V_{IN} \times T_{on} / (2 \times L)$  .....Formula6

$ILx_{max} = I_{OUT} \times V_{OUT} / V_{IN} + V_{IN} \times T_x (V_{OUT}-V_{IN}) / (2 \times L \times V_{OUT})$  .....Formula7

Therefore, peak current is more than  $I_{OUT}$ . Considering the value of  $ILx_{max}$ , the condition of input and output, and external components should be selected.

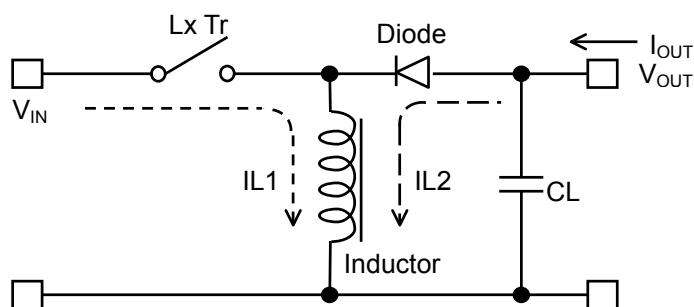

The explanation above is based on the ideal calculation, and the loss caused by Lx switch and external components is not included.

The actual maximum output current is between 50% and 80% of the calculation.

Especially, when the  $IL$  is large, or  $V_{IN}$  is low, the loss of  $V_{IN}$  is generated with on resistance of the switch. As for  $V_{OUT}$ ,  $V_F$ (as much as 0.3V)of the diode should be considered.

## Operation of Inverting DC/DC Converter and Output Current

<Basic Circuit>

<Current through L>

There are also two operation modes for the PWM control inverting switching regulator, that is the continuous mode and the discontinuous mode.

When the LX Tr. is on, the voltage for the inductor L will be VIN. The inductor current (IL1) will be;

$$IL1 = V_{IN} \times T_{on} / L \dots \dots \dots \text{Formula8}$$

Inverting circuit saves energy during on time of Lx Tr, and supplies the energy to output during off time, output voltage opposed to input voltage is obtained. The inductor current at off (IL2) will be;

$$IL2 = V_{OUT} \times T_f / L \dots \dots \dots \text{Formula9}$$

(The above formula and after, the absolute value of the negative output voltage is assumed to be VOUT. : Output voltage= -10V, VOUT=10 )

In terms of the PWM control, when the Tf=Toff, the inductor current will be continuous, the operation of the switching regulator will be continuous mode.

In the continuous mode, the current variation of IL1 and IL2 are same, therefore

$$V_{IN} \times T_{on} / L = V_{OUT} \times T_{off} / L \dots \dots \dots \text{Formula10}$$

In the continuous mode, the duty cycle will be:

$$\text{DUTY} = T_{on} / (T_{on} + T_{off}) = V_{OUT} / (V_{OUT} + V_{IN}) \dots \dots \dots \text{Formula11}$$

If the input power equals to output power,

$$I_{OUT} = V_{IN}^2 \times T_{on} / (2 \times L \times V_{OUT}) \dots \dots \dots \text{Formula12}$$

When IOUT becomes more then Formula12 , it will be continuous mode.

In this moment ,the peak current, ILxmax flowing through the inductor is described as follows:

$$IL_{x\max} = I_{OUT} \times V_{OUT} / V_{IN} + V_{IN} \times T_{on} / (2 \times L) \dots \dots \dots \text{Formula13}$$

$$IL_{x\max} = I_{OUT} \times V_{OUT} / V_{IN} + V_{IN} \times V_{OUT} \times T / \{ 2 \times L \times (V_{OUT} + V_{IN}) \} \dots \dots \dots \text{Formula14}$$

Therefore, peak current is more than IOUT. Considering the value of ILxmax, the condition of input and output, and external components should be selected.

The explanation above is based on the ideal calculation, and the loss caused by Lx switch and external components is not included.

The actual maximum output current is between 50% and 80% of the calculation.

Especially, when the IL is large, or VIN is low, the loss of VIN is generated with on resistance of the switch. As for VOUT, VF(as much as 0.3V)of the diode should be considered.
